(57) Abstract

An enzymatic nucleic acid molecule which cleaves an immunodeficiency virus RNA in a gene required for viral replication, e.g., the *nef* or *tat* gene regions.

DESCRIPTION

Method and Reagent for Inhibiting
Human Immunodeficiency Virus Replication

Background of the Invention

This application is a continuation-in-part of Draper, U.S. Serial No. 07/882,886, filed May 14, 1992, and U.S. Serial No. 08/103,423, filed August 6, 1993, both entitled

5 "Method and Reagent for Inhibiting Human Immunodeficiency Virus Replication," assigned to the same assignee as the present application, the whole of which (including drawings) are hereby incorporated by reference herein and are abandoned in favor of the present application.

10 This invention relates to the use of ribozymes as inhibitors of human immunodeficiency virus (HIV) replication, and in particular, the inhibition of HIV-1 replication. See e.g., Draper et al., PCT/WO93/23569 hereby incorporated by reference.

15 Acquired immunodeficiency syndrome (AIDS) is thought to be caused by infection with the virus HIV-1. At present, it is treated by administration of the drug azidothymidine (AZT), which is thought to slow the progress of, but not cure, the disease. AZT resistant 20 strains of HIV-1 are found to develop after a year of treatment. In some patients AZT has limited efficacy and may be found intolerable. More recently, drugs such as dideoxyinosine (DDI) and dideoxycytidine (DDC) have been tested as treatments for AIDS. None of these compounds 25 reduce the viral load in patients, but they do treat the disease symptoms.

The following is a discussion of relevant art, none of which is admitted to be prior art to the pending claims. Rossi et al., 8 Aids Research and Human 30 Retroviruses 183, 1992, provide a review of the use of ribozymes as anti-HIV-1 therapeutic agents. They state:

5 An emerging strategy in the treatment of viral infections is the use of antisense DNA or RNA to pair with, and block expression of viral transcripts. RNA, in addition to being an informational molecule, can also possess enzymatic activity. Thus, by combining anti-sense and enzymatic functions into a single transcript, it is now possible to design catalytic RNAs, or 10 ribozymes, which can specifically pair with virtually any viral RNA, and cleave the phosphodiester backbone at a specified location, thereby functionally inactivating the viral RNA. In carrying out this cleavage, the ribozyme is 15 not itself altered, and is thus capable of recycling and cleaving other molecules, making it a true enzyme. There are several different catalytic motifs which possess enzymatic activity, and each one of these can be incorporated into an enzymatic antisense with site-specific 20 cleavage capabilities.

Rossi et al. also state that studies have demonstrated that a hammerhead ribozyme targeted to the *gag* gene RNA in the vicinity of the translational initiation codon is capable of specifically cleaving that target in 25 a complex milieux of total cellular RNA. With reference to identification of ribozyme targets in HIV-1 they state that mRNAs for the two regulatory proteins *tat* and *rev* are clearly targets of choice, and that they are examining potential ribozyme cleavage sites in the *tat* mRNA, as well 30 as in the exon shared by *tat* and *rev*. In addition, they state:

A rational approach to the problem of target selection involves the following criteria. First, one should select a functionally 35 important target, such as *tat*, *rev*, *int*, *psi* (packaging site), or the tRNA^{lys} priming site. Once a gene or target region has been decided

upon, the nucleotide sequence should be assessed for strong conservation of sequence among the various isolates. Within these conserved regions, the potential cleavage sites, preferably GUC or GUA (others will suffice, but appear to be less efficiently cleaved) should be chosen. The region should be examined for potential secondary structures, and then the most promising sites chosen. Finally, before testing the ribozyme in cell culture, it is advisable to carry out a series of in vitro cleavage reactions (preferably kinetic analyses) using long (at least 100 nucleotides in length) substrates to verify that the chosen sites are truly structurally favorable for cleavage.

15 [Citation omitted.]

Rossi et al. further state that a target which deserves further consideration and testing as a potential ribozyme cleavage site is the viral packaging signal or 20 psi sequence.

Sioud and Drlica, 88 Proc. Natl. Acad. Sci. USA 7303, 1991 describe ribozymes designed to cleave the integrase gene of HIV. They state that when the ribozyme is transcribed from a plasmid in *E. coli* it leads to destruction 25 of the integrase RNA and complete blockage of integrase protein synthesis. They state that the HIV-1 integrase gene may be a useful target for therapeutic ribozymes.

Heidenreich and Eckstein, 267 Journal of Biological Chemistry 1904, 1992, describe three ribozymes targeted to 30 different sites on the long terminal repeat (LTR) RNA of HIV-1. They also describe the influence of chemical modifications within the ribozyme on the cleavage of the LTR RNA, including 2'-Fluorocytidine substitutions and phosphorothioate internucleotidic linkages.

35 Weerasinghe et al., 65 Journal of Virology 5531, 1991, describe ribozymes designed against a conserved region within the 5' leader sequence of HIV-1 RNA.

Chang et al., 2 Clinical Biotechnology 23, 1990, describe ribozymes designed to target two different sites in the HIV-1 *gag* gene, and a single site in the viral 5'-LTR region.

5 Lorentzen et al., 5 Virus Genes 17, 1991, describe a ribozyme targeted to the virion infectivity factor (*vif*) of HIV-1.

10 Sarver et al., 247 Science 1222, 1990, describe 15 ribozymes in the hammerhead family targeted to HIV-1 *gag* transcripts. They state that cells challenged with HIV-1 showed a substantial reduction in the level of HIV-1 *gag* RNA relative to that in nonribozyme-expressing cells, and that the reduction in *gag* RNA was reflected by a reduction 20 in antigen p24 levels. They state that the results suggest the feasibility of developing ribozymes as therapeutic agents against human pathogens such as HIV-1.

25 Hampel et al., "RNA Catalyst for Cleaving Specific RNA Sequences," filed September 20, 1989, which is a continuation-in-part of U.S. Serial No. 07/247,100, filed September 20, 1988, describe hairpin ribozymes, and provides an example of such a ribozyme apparently specific to the *gag* gene of HIV-1. Hampel and Tritz, 28 Biochemistry 4929, 1989 and Hampel et al., 18 Nucleic Acids Research 299, 1990 also describe hairpin catalytic RNA models and state that one target site is the *tat* gene in HIV-1.

30 Goldberg et al., WO 91/04319 and Robertson and Goldberg WO 91/04324, describe ribozymes expressed within a hepatitis delta vector and state that the genome of the delta virus may carry a ribozyme against the *env* or *gag* mRNA of HIV. Rossi et al., WO 91/03162, describe chimeric DNA-RNA catalytic sequences used to cleave HIV-1 *gag* transcript or the 5' LTR splice site.

35 Ojwang et al., 89 Proc. Natl. Acad. Sci. USA 10, 802, 1992 and Yu et al., 90 Proc. Natl. Acad. Sci. USA 6340, 1993 describe a hairpin ribozyme allegedly able to inhibit HIV-1 expression. Joseph and Burke 268 J. Biol. Chem. 24,

515 1993, describe optimization of an anti-HIV hairpin ribozyme. Dropulic et al., 66 J. Virology 1432, 1992 describe a U5 ribozyme which cleaves at nucleoside +115 in HIV-1 RNA.

Salzman et al., Vol. 2, The Viruses, Plenum Press, NY 1987.

15 Ribozymes are RNA molecules having an enzymatic activity which is able to repeatedly cleave other separate RNA molecules in a nucleotide base sequence specific manner. Such enzymatic RNA molecules can be targeted to virtually any RNA transcript, and efficient cleavage has 20 been achieved *in vitro*. Kim et al., 84 Proc. Natl. Acad. Sci. USA 8788, 1987; Haseloff and Gerlach, 334 Nature 585, 1988; Cech, 260 JAMA 3030, 1988; and Jefferies et al., 17 Nucleic Acids Research 1371, 1989.

25 Ribozymes act by first binding to a target RNA. Such binding occurs through the target RNA binding portion of a ribozyme which is held in close proximity to an enzymatic portion of the RNA which acts to cleave the target RNA. Thus, the ribozyme first recognizes and then binds a target RNA through complementary base-pairing, and once 30 bound to the correct site, acts enzymatically to cut the target RNA. Strategic cleavage of such a target RNA will destroy its ability to direct synthesis of an encoded protein. After a ribozyme has bound and cleaved its RNA target it is released from that RNA to search for another 35 target and can repeatedly bind and cleave new targets.

The enzymatic nature of a ribozyme is advantageous over other technologies, such as antisense technology

(where a nucleic acid molecule simply binds to a nucleic acid target to block its translation) since the effective concentration of ribozyme necessary to effect a therapeutic treatment is lower than that of an antisense oligonucleotide. This advantage reflects the ability of the ribozyme to act enzymatically. Thus, a single ribozyme molecule is able to cleave many molecules of target RNA. In addition, the ribozyme is a highly specific inhibitor, with the specificity of inhibition depending not only on the base pairing mechanism of binding, but also on the mechanism by which the molecule inhibits the expression of the RNA to which it binds. That is, the inhibition is caused by cleavage of the RNA target and so specificity is defined as the ratio of the rate of cleavage of the targeted RNA over the rate of cleavage of non-targeted RNA. This cleavage mechanism is dependent upon factors additional to those involved in base pairing. Thus, it is thought that the specificity of action of a ribozyme is greater than that of antisense oligonucleotide binding the same RNA site.

Summary of the Invention

The invention features novel enzymatic RNA molecules, or ribozymes, and methods for their use for inhibiting immunodeficiency virus replication, e.g., HIV-1, HIV-2 and related viruses including FIV-1 and SIV-1. Such ribozymes can be used in a method for treatment of diseases caused by these related viruses in man and other animals. The invention also features cleavage of the RNA of these viruses by use of ribozymes. In particular, the ribozyme molecules described are targeted to the *LTR*, *nef*, *vif*, *tat* and *rev* viral genes or regions. These genes are known in the art, see, e.g., Matsukura et al., 86 Proc. Natl. Acad. Sci. USA 4244, 1989; Cheng-Mayer et al., 246 Science 1629, 1989; Viscidi et al., 246 Science 1606, 1989; Malim et al., 86 Proc. Natl. Acad. Sci. USA 8222, 1989; Terwilliger

et al., 88 Proc. Natl. Acad. Sci. USA 10971, 1991; and Bartel et al., 67 Cell 529, 1991, and Figs. 2A and 2B.

Thus, in a first aspect, the invention features an enzymatic RNA molecule (or ribozyme) which cleaves HIV-1 RNA, or its equivalent, regions required for viral replication, e.g., protein synthesis, e.g., the *vif*, *nef*, *tat* or *rev* gene regions, or at structures known to regulate viral gene expression, e.g., *tar*, *rre* or 3'-LTR regions.

By "enzymatic RNA molecule" it is meant an RNA molecule which has complementarity in a substrate binding region to a specified gene target, and also has an enzymatic activity which is active to specifically cleave RNA in that target. That is, the enzymatic RNA molecule is able to intermolecularly cleave RNA and thereby inactivate a target RNA molecule. This complementarity functions to allow sufficient hybridization of the enzymatic RNA molecule to the target RNA to allow the cleavage to occur. One hundred percent complementarity is preferred, but complementarity as low as 50-75% may also be useful in this invention. By "equivalent" RNA to HIV-1 is meant to include those naturally occurring RNA molecules associated with immunodeficiency diseases in various animals, including humans, felines, and simians. These viral RNAs have similar structures and equivalent genes to each other, including the *vif*, *nef*, *tat* and *rev* genes.

By "gene" is meant to refer to either the protein coding regions of the cognate mRNA, HIV genome, proviral genome or any regulatory regions in the RNA which regulate synthesis of the protein or stability of the mRNA.

In preferred embodiments, the enzymatic RNA molecule is formed in a hammerhead motif, but may also be formed in the motif of a hairpin, hepatitis delta virus, group I intron or RNaseP-like RNA (in association with an RNA guide sequence). Examples of such hammerhead motifs are described by Rossi et al. (see citations above), of hairpin motifs by Hampel et al. (see citations above), and an example of the hepatitis delta virus motif is described

by Perrotta and Been, 31 Biochemistry 16, 1992; of the RNaseP motif by Guerrier-Takada, et al., 35 Cell 849, 1983; and of the group I intron by Cech et al., U.S. Patent 4,987,071. These specific motifs are not limiting 5 in the invention and those skilled in the art will recognize that all that is important in an enzymatic RNA molecule of this invention is that it has a specific substrate binding site which is complementary to one or more of the target gene RNA regions, and that it have 10 nucleotide sequences within or surrounding that substrate binding site which impart an RNA cleaving activity to the molecule.

In particularly preferred embodiments, the RNA which is cleaved in HIV-1 RNA is selected from one or more of 15 the following sequences:

Sequence taken from the HIVPCV12 sequence in the Los Alamos Human Retrovirus and AIDS database. The sequence folded began at nucleotide number one of the 2.3 kb subgenomic mRNA. This region includes the coding regions 20 for the vif, vpr, vpu, tat, rev, and nef gene products.

In a second related aspect, the invention features a mammalian cell which includes an enzymatic RNA molecule as described above. Preferably, the mammalian cell is a 20 human cell, for example, a T4 lymphocyte having a CD4 receptor molecule on its cell surface.

In a third related aspect, the invention features an expression vector which includes nucleic acid encoding the enzymatic RNA molecules described above, located in the 25 vector, e.g., in a manner which allows expression of that enzymatic RNA molecule within a mammalian cell.

In a fourth related aspect, the invention features a method for treatment of human immunodeficiency disease by administering to a patient an enzymatic RNA molecule which 30 cleaves HIV-1 RNA or related RNA in the *vif*, *nef*, *tat* or *rev* gene regions.

In other related aspects, the invention features treatment of cats or simians with ribozymes of this invention. Such ribozymes may be identical to those able 35 to cleave HIV-1 RNA, or may be modified to target analogous locations in FIV and SIV virus RNAs.

The invention provides a class of chemical cleaving agents which exhibit a high degree of specificity for the viral RNA of HIV-1 type virus-infected cells. If desired, such ribozymes can be designed to target equivalent 5 single-stranded DNAs by methods known in the art. The ribozyme molecule is preferably targeted to a highly conserved sequence region of HIV-1 such that all strains of HIV-1 can be treated with a single ribozyme. Such enzymatic RNA molecules can be delivered exogenously or 10 endogenously to infected cells. In the preferred hammerhead motif, the small size (less than 40 nucleotides, preferably between 32 and 36 nucleotides in length) of the molecule allows the cost of treatment to be reduced compared to other ribozyme motifs.

15 The smallest ribozyme delivered for treatment of HIV infection reported to date (by Rossi et al., 1992, *supra*) is an *in vitro* transcript having a length of 142 nucleotides. Synthesis of ribozymes greater than 100 nucleotides in length is very difficult using automated methods, 20 and the therapeutic cost of such molecules is prohibitive. Delivery of ribozymes by expression vectors is primarily feasible using only *ex vivo* treatments. This limits the utility of this approach. In this invention, an alternative approach uses smaller ribozyme motifs (*e.g.*, of the 25 hammerhead structure, shown generally in Fig. 1) and exogenous delivery. The simple structure of these molecules also increases the ability of the ribozyme to invade targeted regions of the mRNA structure. Thus, unlike the situation when the hammerhead structure is included within 30 longer transcripts, there are no non-ribozyme flanking sequences to interfere with correct folding of the ribozyme structure, or with its complementary binding of the ribozyme to the mRNA target region.

The enzymatic RNA molecules of this invention can be 35 used to treat human immunodeficiency virus infections, including those caused by both HIV-1 and HIV-2. Such treatment can also be extended to other related viruses

which infect non-human primates including the simian and feline immunodeficiency viruses. Infected animals can be treated at the time of productive infection. This timing of treatment will reduce viral loads in infected cells and 5 disable viral replication in any subsequent rounds of infection. This is possible because the ribozymes disable those structures required for successful initiation of viral protein synthesis.

The targets chosen in the present invention provide 10 a distinct advantage over prior targets since they act not only at the time of viral absorption or reverse transcription during infection, but also in latently infected cells and in virally transformed cells. In addition, viral particles which are released during a first round of 15 infection in the presence of such ribozymes will still be immunogenic by virtue of having their capsids intact. Thus, one method of this invention allows the creation of defective but immunogenic viral particles, and thus a continued possibility of initiation of an immune response 20 in a treated animal.

In addition, the enzymatic RNA molecules of this invention can be used *in vitro* in a cell culture infected with HIV-1 viruses, or related viruses, to produce viral particles which have intact capsids and defective genomic 25 RNA. These particles can then be used for instigation of immune responses in a prophylactic manner, or as a treatment of infected animals.

The invention also features immunization preparations formed from defective HIV-1 particles (or related 30 particles) created by a method of this invention, and methods for immunization or vaccination using these defective particles, e.g., with DNA or vectors encoding a ribozyme of this invention under the control of a suitable promoter.

Diagnostic uses

Ribozymes of this invention may be used as diagnostic tools to examine genetic drift and mutations of viruses within diseased cells. The close relationship between 5 ribozyme activity and the structure of the target RNA allows the detection of mutations in any region of the molecule which alters the base-pairing and three-dimensional structure of the target RNA. By using multiple ribozymes described in this invention, one may 10 map nucleotide changes which are important to RNA structure and function *in vitro*, as well as in cells and tissues. Cleavage of target RNAs with ribozymes may be used to inhibit gene expression and define the role (essentially) of specified gene products in the progression 15 of disease. In this manner, other genetic targets may be defined as important mediators of the disease. These experiments will lead to better treatment of the disease progression by affording the possibility of combinational therapies (e.g., multiple ribozymes targeted 20 to different genes, ribozymes coupled with known small molecule inhibitors, or intermittent treatment with combinations of ribozymes and/or other chemical or biological molecules). Other *in vitro* uses of ribozymes of this invention are well known in the art, and include detection 25 of the presence of mRNA associated with an HIV-1 related condition. Such RNA is detected by determining the presence of a cleavage product after treatment with a ribozyme using standard methodology.

In a specific example, ribozymes which can cleave 30 only wild-type HIV or mutant forms of the target RNA are used for the assay. The first ribozyme is used to identify wild-type RNA present in the sample and the second ribozyme will be used to identify mutant RNA in the sample. As reaction controls, synthetic substrates of 35 both wild-type and mutant RNA will be cleaved by both ribozymes to demonstrate the relative ribozyme efficiencies in the reactions and the absence of cleavage of

the "non-targeted" RNA species. The cleavage products from the synthetic substrates will also serve to generate size markers for the analysis of wild-type and mutant RNAs in the sample population. Thus each analysis will 5 require two ribozymes, two substrates and one unknown sample which will be combined into six reactions. The presence of cleavage products will be determined using an RNase protection assay so that full-length and cleavage fragments of each RNA can be analyzed in one lane of a 10 polyacrylamide gel. It is not absolutely required to quantify the results to gain insight into the expression of mutant RNAs and putative risk of the desired phenotypic changes in target cells. The expression of mRNA whose 15 protein product is implicated in the development of the phenotype (i.e., HIV) is adequate to establish risk. If probes of comparable specific activity are used for both transcripts, then a qualitative comparison of RNA levels will be adequate and will decrease the cost of the initial 20 diagnosis. Higher mutant form to wild-type ratios will be correlated with higher risk whether RNA levels are compared qualitatively or quantitatively.

Other features and advantages of the invention will be apparent from the following description of the preferred embodiments thereof, and from the claims.

25 Description of the Preferred Embodiments

The drawings will first briefly be described.

Drawings

Fig. 1 is a diagrammatic representation of a hammer-head motif ribozyme showing stems I, II and III (marked 30 (I), (II) and (III) respectively) interacting with an HIV-1 target region. The 5' and 3' ends of both ribozyme and target are shown. Dashes indicate base-paired nucleotides.

Figs. 2A and 2B are diagrammatic representations of 35 the various genes and gene regions in HIV-1 and HIV-2.

Figs. 3A - 3C are diagrammatic representations of three ribozymes of this invention.

Figs. 4A - 4G are diagrammatic representations of chemically modified ribozymes of this invention (solid 5 circles indicate modified bases). Specifically, Fig. 4A is unmodified HCH-r37, Fig. 4B is Thio-substituted HCH-r37S2, Fig. 4C is Thio-substituted HCH-r37S4, Figs. 4D - G are Thio substituted HCH-s37A - D.

Fig. 5 is a diagrammatic representation of a 10 chemically modified ribozyme of this invention (circled bases are modified with 2'-O-methyl), specifically the bases are modified with 2'-O-methyl HCH-037A.

Figs. 6a-6f are graphical representations of ribozyme 15 stability in Vero cell or HeLa cell extracts from cytoplasm, membrane, and nucleus.

Figs. 7, 8 and 9 are diagrammatic representations of various hammerhead ribozymes along with data on activity, and nuclease resistance.

Fig. 10 is a graphical representation of activity of 20 various LTR-targeted ribozymes.

Fig. 11 is a graphical representation of activity of ribozymes of various arm lengths.

Fig. 12 is a graphical representation of ribozymes with different sugar modifications.

25 Fig. 13 is a graphical representation of activity of various TAT-targeted ribozymes.

Fig. 14 is a diagrammatic representation of a hammerhead ribozyme showing base numbering. Each N and N' can be the same or different.

30 Fig. 15 is a diagrammatic representation of two hairpin ribozymes active on HIV RNA.

Target Sites

The genome of HIV-1 is subject to rapid genetic drift by virtue of its RNA content and the nature of errors in 35 reverse transcription. Those regions (genes) of the genome which are essential for virus replication, however,

are expected to maintain a constant sequence (*i.e.*, are conserved) over extensive periods of time. These regions are preferred target sites in this invention since they are more likely to be conserved between different types or 5 strains of immunodeficiency viruses, and thus only one ribozyme is needed to destroy all such viruses. Thus, one ribozyme may be used to target all HIV-1 virus, as well as all HIV-2, SIV and FIV viruses. We have selected several such genes of HIV-1, and examined their nucleotide 10 sequences for the presence of conserved regions which may be cleaved by ribozymes targeted to those regions. Two genes analyzed in detail are the *vif* and *nef* genes; the *tat*, *rev* and other genes noted above can be analyzed in a manner similar to that described below. Nucleotide 15 sequences were acquired from the Los Alamos HIV gene bank.

Ribozymes targeting selected regions of the HIV genome are chosen to cleave the target RNA in a manner which inhibits translation of the RNA. Genes are selected such that inhibition of translation will inhibit viral 20 replication, *e.g.*, by inhibiting protein synthesis. Selection of effective target sites within these critical regions of HIV-1 RNA entails testing the accessibility of the target RNA to hybridization with various oligonucleotide probes. These studies can be performed using RNA 25 probes and assaying accessibility by cleaving the hybrid molecule with RNaseH (see below). Alternatively, such a study can use ribozyme probes designed from secondary structure predictions of the RNAs, and assaying cleavage products by polyacrylamide gel electrophoresis (PAGE), to 30 detect the presence of cleaved and uncleaved molecules.

The following is but one example of a method by which suitable target sites can be identified and is not limiting in this invention. Generally, the method involves identifying potential cleavage sites for a hammerhead 35 ribozyme, and then testing each of these sites to determine their suitability as targets by ensuring that secondary structure formation is minimal.

The HIV-1 genomic sequences of the Los Alamos data bank were compared in the regions encoding the *vif* and *nef* genes. Fifteen putative ribozyme cleavage sites were found to be highly conserved between the 11 strains of 5 virus sequence. These sites represent the preferable sites for hammerhead ribozyme cleavage within these two target RNAs. Two of the *nef* gene sites overlap regions within the 3'-LTR of the HIV-1 genome, which represents another target of potential therapeutic value. All of the 10 *nef* targets are present in all known HIV-1 mRNAs and may represent targets for cleavage which would disrupt 3' terminal control regions of the mRNA which may be required for efficient translation or export of the RNAs. In a similar manner, a number of the *vif* target sites are 15 present in the *pol*, *tat* and *vpr* mRNAs (see Fig. 2).

Short RNA substrates corresponding to each of the *vif* and *nef* gene sites were designed. Each substrate was composed of two to three nucleotides at the 5' and 3' ends that would not base pair with a corresponding ribozyme 20 recognition region. The unpaired regions flanked a central region of 12-14 nucleotides to which complementary arms in the ribozyme were designed.

The structure of each substrate sequence was predicted using a standard commercially available PC fold 25 computer program. Sequences which gave a positive free energy of binding were accepted. Sequences which gave a negative free energy were modified by trimming one or two bases from each of the ends. If the modified sequences were still predicted to have a strong secondary structure, 30 they were rejected.

After substrates were chosen, ribozymes were designed to each of the RNA substrates. Ribozyme folding was also analyzed using PC fold.

Ribozyme molecules were sought which formed hammer- 35 head motif stem II (see Fig. 1) regions and contained flanking arms which were devoid of intramolecular base pairing. Often the ribozymes were modified by trimming a

base from the ends of the ribozyme, or by introducing additional base pairs in stem II to achieve the desired fold. Ribozymes with incorrect folding were rejected. After substrate/ribozyme pairs were found to contain 5 correct intramolecular structures, the molecules were folded together to predict intermolecular interactions. A schematic representation of a ribozyme with its coordinate base pairing to its cognate target sequence is shown in Fig. 1.

10 Using such analyses, the following predictions of effective target sites in the *vif* and *nef* genes of the HIV genome, based upon computer generated sequence comparisons, were obtained (see Table 1). The target sequence is listed first with the 5'-most nucleotide number, for 15 reference. Bases in parentheses are alternative bases in the conserved patterns.

Those targets thought to be useful as ribozyme targets can be tested to determine accessibility to nucleic acid probes in a ribonuclease H assay (see below). This assay provides a quick test of the use of the target 10 site without requiring synthesis of a ribozyme. It can be used to screen for sites most suited for ribozyme attack.

Synthesis of Ribozymes

Ribozymes useful in this invention can be produced by gene transcription as described by Cech, *supra*, or by 15 chemical synthesis. Chemical synthesis of RNA is similar to that for DNA synthesis. The additional 2'-OH group in RNA, however, requires a different protecting group strategy to deal with selective 3'-5' internucleotide bond formation, and with RNA susceptibility to degradation in 20 the presence of bases. The recently developed method of RNA synthesis utilizing the t-butyldimethylsilyl group for the protection of the 2' hydroxyl is the most reliable method for synthesis of ribozymes. The method reproducibly yields RNA with the correct 3'-5' internucleotide 25 linkages, with average coupling yields in excess of 99%, and requires only a two-step deprotection of the polymer.

A method, based upon H-phosphonate chemistry exhibits a relatively lower coupling efficiency than a method based upon phosphoramidite chemistry. This is a problem for 30 synthesis of DNA as well. A promising approach to scale-up of automatic oligonucleotide synthesis has been described recently for the H-phosphonates. A combination of a proper coupling time and additional capping of "failure" sequences gave high yields in the synthesis of

oligodeoxynucleotides in scales in the range of 14 μ moles with as little as 2 equivalents of a monomer in the coupling step. Another alternative approach is to use soluble polymeric supports (e.g., polyethylene glycols), instead 5 of the conventional solid supports. This method can yield short oligonucleotides in hundred milligram quantities per batch utilizing about 3 equivalents of a monomer in a coupling step.

Various modifications to ribozyme structure can be 10 made to enhance the utility of ribozymes. Such modifications will enhance shelf-life, half-life *in vitro*, stability, and ease of introduction of such ribozymes to the target site, e.g., to enhance penetration of cellular membranes, and confer the ability to recognize and bind to 15 targeted cells.

Exogenous delivery of ribozymes benefits from chemical modification of the backbone, e.g., by the overall negative charge of the ribozyme molecule being reduced to facilitate diffusion across the cell membrane. The 20 present strategies for reducing the oligonucleotide charge include: modification of internucleotide linkages by methylphosphonates, use of phosphoramidites, linking oligonucleotides to positively charged molecules, and creating complex packages composed of oligonucleotides, 25 lipids and specific receptors or effectors for targeted cells. Examples of such modifications include sulfur-containing ribozymes containing phosphorothioates and phosphorodithioates as internucleotide linkages in RNA. Synthesis of such sulfur-modified ribozymes is achieved by 30 use of the sulfur-transfer reagent, $^3\text{H}-1,2\text{-benzenedithiol-3-one 1,1-dioxide}$. Ribozymes may also contain ribose modified ribonucleotides. Pyrimidine analogues are prepared from uridine using a procedure employing diethyl-amino sulphur trifluoride (DAST) as a starting reagent. 35 Ribozymes can also be either electrostatically or covalently attached to polymeric cations for the purpose of reducing charge. The polymer can be attached to the

ribozyme by simply converting the 3'-end to a ribonucleoside dialdehyde which is obtained by a periodate cleavage of the terminal 2',3'-cis diol system. Depending on the specific requirements for delivery systems, other possible 5 modifications may include different linker arms containing carboxyl, amino or thiol functionalities. Yet further examples include use of methylphosphonates and 2'-O-methylribose and 5' or 3' capping or blocking with m₁GpppG or m_{2,2,7}GpppG.

10 For example, a kinased ribozyme is contacted with guanosine triphosphate and guanyltransferase to add a m⁷G cap to the ribozyme. After such synthesis, the ribozyme can be gel purified using standard procedure. To ensure that the ribozyme has the desired activity, it may be 15 tested with and without the 5' cap using standard procedures to assay both its enzymatic activity and its stability.

20 Synthetic ribozymes, including those containing various modifiers, can be purified by high pressure liquid chromatography (HPLC). Other liquid chromatography techniques, employing reverse phase columns and anion exchangers on silica and polymeric supports may also be used.

25 There follows an example of the synthesis of one ribozyme. A solid phase phosphoramidite chemistry was employed. Monomers used were 2'-tert-butyl-dimethylsilyl cyanoethylphosphoramidites of uridine, N-benzoyl-cytosine, N-phenoxyacetyl adenosine, and guanosine (Glen Research, Sterling, VA).

30 Solid phase synthesis was carried out on either an ABI 394 or 380B DNA/RNA synthesizer using the standard protocol provided with each machine. The only exception was that the coupling step was increased from 10 to 12 minutes. The phosphoramidite concentration was 0.1 M. 35 Synthesis was done on a 1 μmole scale using a 1 μmole RNA reaction column (Glen Research). The average coupling efficiencies were between 97% and 98% for the 394 model,

and between 97% and 99% for the 380B model, as determined by a calorimetric measurement of the released trityl cation.

After synthesis, the blocked ribozymes were cleaved 5 from the solid support (e.g., CPG), and the bases and diphosphoester moiety deprotected in a sterile vial by incubation in dry ethanolic ammonia (2 mL) at 55°C for 16 hours. The reaction mixture was cooled on dry ice. Later, the cold liquid was transferred into a sterile 10 screw cap vial and lyophilized.

To remove the 2'-tert-butyl-dimethylsilyl groups from the ribozyme, the obtained residue was suspended in 1 M tetra-n-butylammonium fluoride in dry THF (TBAF), using a 20-fold excess of the reagent for every silyl group, for 15 16 hours at ambient temperature (about 15-25°C). The reaction was quenched by adding an equal volume of sterile 1 M triethylamine acetate, pH 6.5. The sample was cooled and concentrated on a SpeedVac to half the initial volume.

The ribozymes were purified in two steps by HPLC on 20 a C4 300 Å 5 µm DeltaPak column in an acetonitrile gradient.

The first step, or "trityl on" step, was a separation of 5'-DMT-protected ribozyme(s) from failure sequences lacking a 5'-DMT group. Solvents used for this step were: 25 A (0.1 M triethylammonium acetate, pH 6.8) and B (acetonitrile). The elution profile was: 20% B for 10 minutes, followed by a linear gradient of 20% B to 50% B over 50 minutes, 50% B for 10 minutes, a linear gradient of 50% B to 100% B over 10 minutes, and a linear gradient of 100% 30 B to 0% B over 10 minutes.

The second step was a purification of a completely deblocked ribozyme by a treatment of 2% trifluoroacetic acid on a C4 300 Å 5 µm DeltaPak column in an acetonitrile gradient. Solvents used for this second step were: A 35 (0.1 M Triethylammonium acetate, pH 6.8) and B (80% acetonitrile, 0.1 M triethylammonium acetate, pH 6.8). The elution profile was: 5% B for 5 minutes, a linear

gradient of 5% B to 15% B over 60 minutes, 15% B for 10 minutes, and a linear gradient of 15% B to 0% B over 10 minutes.

The fraction containing ribozyme, which is in the 5 triethylammonium salt form, was cooled and lyophilized on a SpeedVac. Solid residue was dissolved in a minimum amount of ethanol and ribozyme in sodium salt form was precipitated by addition of sodium perchlorate in acetone. (K⁺ or Mg²⁺ salts can be produced in an equivalent manner.) 10 The ribozyme was collected by centrifugation, washed three times with acetone, and lyophilized.

Expression Vector

While synthetic ribozymes are preferred in this invention, those produced by expression vectors can also 15 be used. In designing a suitable ribozyme expression vector the following factors are important to consider. The final ribozyme must be kept as small as possible to minimize unwanted secondary structure within the ribozyme. A promoter (e.g., the human cytomegalovirus immediate 20 early region (HCMV iel) promoter) should be chosen to be a relatively strong promoter, and expressible both in vitro and in vivo. Such a promoter should express the ribozyme at a level suitable to effect production of enough ribozyme to destroy a target RNA, but not at too 25 high a level to prevent other cellular activities from occurring (unless cell death itself is desired).

A hairpin at the 5' end of the ribozyme is useful to ensure that the required transcription initiation sequence (GG or GGG or GGGAG) does not bind to some other part of 30 the ribozyme and thus affect regulation of the transcription process. The 5' hairpin is also useful to protect the ribozyme from 5'-3' exonucleases. A selected hairpin at the 3' end of the ribozyme gene is useful since it acts as a transcription termination signal, and as a protection 35 from 3'-5' exonuclease activity. One example of a known termination signal is that present on the T7 RNA polymer-

ase system. This signal is about 30 nucleotides in length. Other 3' hairpins of shorter length can be used to provide good termination and RNA stability. Such hairpins can be inserted within the vector sequences to 5 allow standard ribozymes to be placed in an appropriate orientation and expressed with such sequences attached.

Poly(A) tails are also useful to protect the 3' end of the ribozyme. These can be provided by either including a poly(A) signal site in the expression vector (to 10 signal a cell to add the poly(A) tail *in vivo*), or by introducing a poly(A) sequence directly into the expression vector. In the first approach, the signal must be located to prevent unwanted secondary structure formation with other parts of the ribozyme. In the second approach, 15 the poly(A) stretch may reduce in size over time when expressed *in vivo*, and thus the vector may need to be checked over time. Care must be taken in addition of a poly(A) tail which binds poly(A) binding proteins which prevent the ribozyme from acting upon their target 20 sequence.

Ribozyme Testing

Once the desired ribozymes are selected, synthesized and purified, they are tested in kinetic and other experiments to determine their utility. An example of such a 25 procedure is provided below.

Preparation of Ribozyme

Crude synthetic ribozyme (typically 350 μ g at a time) is purified by separation on a 15% denaturing polyacrylamide gel (0.75 mm thick, 40 cm long) and visualized by UV 30 shadowing. Once excised, gel slices containing full length ribozyme are soaked in 5 ml gel elution buffer (0.5 M NH_4OAc , 1 mM EDTA) overnight with shaking at 4°C. The eluent is desalted over a C-18 matrix (Sep-Pak cartridges, Millipore, Milford, MA) and vacuum dried. The dried RNA 35 is resuspended in 50-100 μ l TE (TRIS 10 mM, EDTA 1 mM, pH

7.2). An aliquot of this solution is diluted 100-fold into 1 ml TE, half of which is used to spectrophotometrically quantitate the ribozyme solution. The concentration of this dilute stock is typically 150-800 nM. Purity of 5 the ribozyme is confirmed by the presence of a single band on a denaturing polyacrylamide gel.

A ribozyme may advantageously be synthesized in two or more portions. Each portion of a ribozyme will generally have only limited or no enzymatic activity, and the 10 activity will increase substantially (by at least 5-10 fold) when all portions are ligated (or otherwise juxtaposed) together. A specific example of hammerhead ribozyme synthesis is provided below.

The method involves synthesis of two (or more) 15 shorter "half" ribozymes and ligation of them together using T4 RNA ligase. For example, to make a 34 mer ribozyme, two 17 mers are synthesized, one is phosphorylated, and both are gel purified. These purified 17 mers are then annealed to a DNA splint strand complementary to the 20 two 17 mers. This DNA splint has a sequence designed to locate the two 17 mer portions with one end of each adjacent each other. The juxtaposed RNA molecules are then treated with T4 RNA ligase in the presence of ATP. Alternatively, the DNA splint strand may be omitted from 25 the ligation reaction if the complementary binding affects favorable ligation of the two RNA molecules. The 34 mer RNA so formed is then HPLC purified.

Preparation of Substrates

Approximately 10-30 pmoles of unpurified substrate is 30 radioactively 5' end-labeled with T4 polynucleotide kinase using 25 pmoles of [γ -³²P] ATP. The entire labeling mix is separated on a 20% denaturing polyacrylamide gel and visualized by autoradiography. The full length band is excised and soaked overnight at 4°C in 100 μ l of TE (10 mM 35 Tris-HCl pH 7.6, 0.1 mM EDTA).

Kinetic Reactions

For reactions using short substrates (between 8 and 16 bases) a substrate solution is made 1X in assay buffer (75 mM Tris-HCl, pH 7.6; 0.1 mM EDTA, 10 mM MgCl₂) such that the concentration of substrate is less than 1 nM. A ribozyme solution (typically 20 nM) is made 1X in assay buffer and four dilutions are made using 1X assay buffer. Fifteen μ l of each ribozyme dilution (i.e., 20, 16, 12, 8 and 4 nM) is placed in a separate tube. These tubes and the substrate tube are pre-incubated at 37°C for at least five minutes.

The reaction is started by mixing 15 μ l of substrate into each ribozyme tube by rapid pipetting (note that final ribozyme concentrations are 10, 8, 6, 4, 2 nM). Five μ l aliquots are removed at 15 or 30 second intervals and quenched with 5 μ l stop solution (95% formamide, 20 mM EDTA xylene cyanol, and bromphenol blue dyes). Following the final ribozyme time point, an aliquot of the remaining substrate is removed as a zero ribozyme control.

The samples are separated on either 15% or 20% polyacrylamide gels. Each gel is visualized and quantitated with an Ambis beta scanner (Ambis Systems, San Diego, CA).

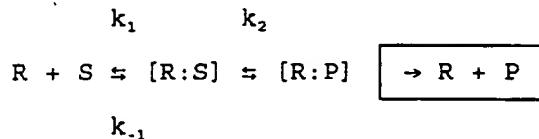

For the most active ribozymes, kinetic analyses are performed in substrate excess to determine K_m and K_{cat} values.

For kinetic reactions with long RNA substrates (greater than 15 bases in length) the substrates are prepared by transcription using T7 RNA polymerase and defined templates containing a T7 promoter, and DNA encoding appropriate nucleotides of the HIV-1 RNA. The substrate solution is made 1X in assay buffer (75 mM Tris-HCl, pH 7.6; 0.1 mM EDTA; 10 mM MgCl₂) and contains 58 nanomolar concentration of the long RNA molecules. The reaction is started by addition of gel purified ribozymes to 1 μ M concentration. Aliquots are removed at 20, 40, 60, 80 and 100 minutes, then quenched by the addition of 5 μ l stop solution. Cleavage products are separated using

denaturing PAGE. The bands are visualized and quantitated with an Ambis beta scanner.

Kinetic Analysis

A simple reaction mechanism for ribozyme-mediated cleavage is:

10

where R = ribozyme, S = substrate, and P = products. The boxed step is important only in substrate excess. Because ribozyme concentration is in excess over substrate concentration, the concentration of the ribozyme-substrate complex ($[R:S]$) is constant over time except during the very brief time when the complex is being initially formed, i.e. :

$$\frac{d[R:S]}{dt} = 0$$

20 where t = time, and thus:

$$(R)(S)k_1 = (RS)(k_2 + k_1).$$

The rate of the reaction is the rate of disappearance of substrate with time:

$$\text{Rate} = \frac{-d(S)}{dt} = k_2(RS)$$

25

Substituting these expressions:

$$(R)(S)k_1 = 1/k_2 \frac{-d(S)}{dt} (k_2 + k_1)$$

or:

$$30 \quad \frac{-d(S)}{S} = \frac{k_1 k_2}{(k_2 + k_1)} (R) dt$$

Integrating this expression with respect to time yields:

$$-\ln \frac{S}{S_0} = \frac{k_1 k_2}{(k_2 + k_1)} (R) t$$

35 where S_0 = initial substrate. Therefore, a plot of the negative log of fraction substrate uncut versus time (in minutes) yields a straight line with slope:

$$\text{slope} = \frac{k_1 k_2}{(k_2 + k_1)} (R) = k_{\text{obs}}$$

where k_{obs} = observed rate constant. A plot of slope (k_{obs}) versus ribozyme concentration yields a straight line with a slope which is:

$$5 \quad \text{slope} = \frac{k_1 k_2}{(k_2 + k_1)} \quad \text{which is} \quad \frac{k_{\text{cat}}}{K_m}$$

Using these equations the data obtained from the kinetic experiments provides the necessary information to determine which ribozyme tested is most useful, or active. Such ribozymes can be selected and tested in *in vivo* or 10 *ex vivo* systems.

Liposome Preparation

Lipid molecules were dissolved in a volatile organic solvent (CHCl₃, methanol, diethylether, ethanol, etc.). The organic solvent was removed by evaporation. The lipid was hydrated into suspension with 0.1x phosphate buffered saline (PBS), then freeze-thawed 3x using liquid nitrogen and incubation at room temperature. The suspension was extruded sequentially through a 0.4 μm, 0.2 μm and 0.1 μm polycarbonate filters at maximum pressure of 800 psi. The ribozyme was mixed with the extruded liposome suspension and lyophilized to dryness. The lipid/ribozyme powder was rehydrated with water to one-tenth the original volume. The suspension was diluted to the minimum volume required for extrusion (0.4 ml for 1.5 ml barrel and 1.5 ml for 10 ml barrel) with 1xPBS and re-extruded through 0.4 μm, 0.2 μm, 0.1 μm polycarbonate filters. The liposome entrapped ribozyme was separated from untrapped ribozyme by gel filtration chromatography (SEPHAROSE CL-4B, BIOGEL A5M). The liposome extractions were pooled and sterilized by filtration through a 0.2 μm filter. The free ribozyme was pooled and recovered by ethanol precipitation. The liposome concentration was determined by incorporation of a radioactive lipid. The ribozyme concentration was determined by labeling with ³²P. Rossi et al., 1992, *supra* (and references cited therein), describe other methods suitable for preparation of liposomes.

In experiments with a liposome formulation composed of a synthetic lipid derivative distearoyl-phosphatidyl-ethylamidotnioacetyl succinimide (DSPE-ATS) co-formulated with dipalmitoylphosphatidyl choline and cholesterol we 5 observed uptake of 100 and 200 nm diameter liposomes with similar kinetics. The larger particles accommodated a larger number of entrapped molecules, or larger molecular weight molecules, such as an expression plasmid. These 10 particles showed a linear relationship between the lipid dose offered and the mean log fluorescence (calcein was used to follow liposome uptake). No cytotoxicity was observed even with a 200 μ M dose. These liposomes are particularly useful for delivery to CD4 cell populations.

In Vivo Assay

15 The efficacy of action of a chosen ribozyme may be tested *in vivo* by use of cell cultures sensitive to HIV-1 or a related virus, using standard procedures. For example, monolayer cultures of HIV-sensitive cells are grown by established procedures. Cells are grown in 6 or 20 96 well tissue culture plates. Prior to infection with HIV, cultures are treated for 3 to 24 hours with ribozyme-containing liposomes. Cells are then rinsed with phosphate buffered saline (PBS) and virus added at a multiplicity of 1-100 pfu/cell. After a one-hour adsorption, 25 free virus is rinsed away using PBS, and the cells are treated for three to five days with appropriate liposome preparations. Cells are then re-fed with fresh medium and re-incubated. Virus is harvested from cells into the overlying medium. Cells are broken by three cycles of 30 incubation at -70°C and 37°C for 30 minutes at each temperature, and viral titers determined by plaque assay using established procedures.

Ribonuclease Protection Assay

The accumulation of target mRNA in cells or the 35 cleavage of the RNA by ribozymes or RNaseH (*in vitro* or

in vivo) can be quantified using an RNase protection assay.

In this method, antisense riboprobes are transcribed from template DNA using T7 RNA polymerase (U.S. 5 Biochemical) in 20 μ l reactions containing 1X transcription buffer (supplied by the manufacturer), 0.2 mM ATP, GTP and UTP, 1 U/ μ l pancreatic RNase inhibitor (Boehringer Mannheim Biochemicals) and 200 μ Ci 32 P-labeled CTP (800 Ci/mmol, New England Nuclear) for 1 hour at 37°C. 10 Template DNA is digested with 1 U RNase-free DNaseI (U.S. Biochemical, Cleveland, OH) at 37°C for 15 minutes and unincorporated nucleotides removed by G-50 SEPHADEX spin chromatography.

In a manner similar to the transcription of antisense 15 probe, the target RNA can be transcribed *in vitro* using a suitable DNA template. The transcript is purified by standard methods and digested with ribozyme at 37°C according to methods described later.

Alternatively, virus-infected cells are harvested 20 into 1 ml of PBS, transferred to a 1.5 ml EPPENDORF tube, pelleted for 30 seconds at low speed in a microcentrifuge, and lysed in 70 μ l of hybridization buffer (4 M guanidine isothiocyanate, 0.1% sarcosyl, 25 mM sodium citrate, pH 7.5). Cell lysate (45 μ l) or defined amounts of *in vitro* 25 transcript (also in hybridization buffer) is then combined with 5 μ l of hybridization buffer containing 5×10^5 cpm of each antisense riboprobe in 0.5 ml Eppendorf tubes, overlaid with 25 μ l mineral oil, and hybridization accomplished by heating overnight at 55°C. The hybridization 30 reactions are diluted into 0.5 ml RNase solution (20 U/ml RNaseA, 2 U/ml RNaseT1, 10 U/ml RNase-free DNaseI in 0.4 M NaCl), heated for 30 minutes at 37°C, and 10 μ l of 20% SDS and 10 μ l of Proteinase K (10 mg/ml) added, followed by an additional 30 minutes incubation at 37°C. Hybrids 35 are partially purified by extraction with 0.5 ml of a 1:1 mixture of phenol/chloroform; aqueous phases are combined with 0.5 ml isopropanol, and RNase-resistant hybrids

pelleted for 10 minutes at room temperature (about 20°C) in a microcentrifuge. Pellets are dissolved in 10 μ l loading buffer (95% formamide, 1X TBE, 0.1% bromophenol blue, 0.1% xylene cyanol), heated to 95°C for five minutes, cooled on ice, and analyzed on 4% polyacrylamide/7 M urea gels under denaturing conditions.

Ribozyme Stability

The chosen ribozyme can be tested to determine its stability, and thus its potential utility. Such a test 10 can also be used to determine the effect of various chemical modifications (e.g., addition of a poly(A) tail) on the ribozyme stability and thus aid selection of a more stable ribozyme. For example, a reaction mixture contains 1 to 5 pmoles of 5' (kinased) and/or 3' labeled ribozyme, 15 15 μ g of cytosolic extract and 2.5 mM MgCl₂ in a total volume of 100 μ l. The reaction is incubated at 37°C. Eight μ l aliquots are taken at timed intervals and mixed with 8 μ l of a stop mix (20 mM EDTA, 95% formamide). Samples are separated on a 15% acrylamide sequencing gel, 20 exposed to film, and scanned with an Ambis.

A 3'-labeled ribozyme can be formed by incorporation of the ³²P-labeled cordycepin at the 3' OH using poly(A) polymerase. For example, the poly(A) polymerase reaction contains 40 mM Tris, pH 8, 10 mM MgCl₂, 250 mM NaCl, 2.5 mM 25 MnCl₂; 3 μ l P³² cordycepin, 500 Ci/mM; and 6 units poly(A) polymerase in a total volume of 50 μ l. The reaction mixture is incubated for 30 minutes at 37°C.

Effect of Liposome Surface Modifications on Lymphocyte and Macrophage Uptake

30 Liposomes containing distearoylphosphatidyl ethanol-amidomethyl thioacetate can be prepared. The thiol group can be deprotected using hydroxylamine and the reactive thiol can then be modified with thiol reactive groups to alter the surface properties of the liposomes. Reaction 35 with N-ethylmaleimide leads to lymphocyte and macrophage

uptake. This modification results in liposome uptake by CD4⁺ and CD4⁻ lymphocytes.

Modification with iodoacetamide and iodoacetic acid were tested for uptake. Iodactamide modification showed 5 that the liposomes were toxic in that the lymphocyte cell number decreased with time. However, the acetate uptake was 5-fold greater than that observed for succinimide. Uptake was monitored by both uptake of a ³H-hexadecyl-cholesterol ether and an entrapped water soluble 10 fluorophore, calcein. Both confirmed that the liposomes were being taken up by the cells over a 72 hour period. The uptake was assayed in lymphoblasts which had been stimulated for 72 hours with phytohemagglutinin. The uptake curve was biphasic in that within the first 8 15 hours, only cell surface binding was observed whereas after 24 hours, uptake was linear for up to 72 hours. This was observed for a 200 μ M dose. The 100 μ M lipid dose showed only cell surface binding.

Effect of Base Substitution Upon Ribozyme Activity

20 To determine which primary structural characteristics could change ribozyme cleavage of substrate, minor base changes can be made in the substrate cleavage region recognized by a specific ribozyme. For example, the substrate sequences can be changed at the central "C" 25 nucleotide, changing the cleavage site from a GUC to a GUA motif. The K_{cat}/K_m values for cleavage using each substrate are then analyzed to determine if such a change increases ribozyme cleavage rates. Similar experiments can be performed to address the effects of changing bases complementary to the ribozyme binding arms. Changes predicted 30 to maintain strong binding to the complementary substrate are preferred. Minor changes in nucleotide content can alter ribozyme/substrate interactions in ways which are unpredictable based upon binding strength alone. 35 Structures in the catalytic core region of the ribozyme recognize trivial changes in either substrate structure or

the three dimensional structure of the ribozyme/substrate complex.

To begin optimizing ribozyme design, the cleavage rates of ribozymes containing varied arm lengths, but 5 targeted to the same length of short RNA substrate can be tested. Minimal arm lengths are required and effective cleavage varies with ribozyme/substrate combinations.

The cleavage activity of selected ribozymes can be assessed using HIV-1-homologous substrates. The assays 10 are performed in ribozyme excess and approximate K_{cat}/K_{min} values obtained. Comparison of values obtained with short and long substrates indicates utility *in vivo* of a ribozyme.

Intracellular Stability of Liposome-delivered Ribozymes

15 To test the stability of a chosen ribozyme *in vivo* the following test is useful. Ribozymes are ^{32}P -end-labeled, entrapped in liposomes and delivered to HIV-1 sensitive cells for three hours. The cells are fractionated and ribozyme is purified by phenol/chloroform 20 extraction. Alternatively, cells (1×10^7 , T-175 flask) are scraped from the surface of the flask and washed twice with cold PBS. The cells are homogenized by douncing 35 times in 4 ml of TSE (10 mM Tris, pH 7.4, 0.25 M Sucrose, 1 mM EDTA). Nuclei are pelleted at 100xg for 10 minutes. 25 Subcellular organelles (the membrane fraction) are pelleted at 200,000xg for two hours using an SW60 rotor. The pellet is resuspended in 1 ml of H buffer (0.25 M Sucrose, 50 mM HEPES, pH 7.4). The supernatant contains the cytoplasmic fraction (in approximately 3.7 ml). The 30 nuclear pellet is resuspended in 1 ml of 65% sucrose in TM (50 mM Tris, pH 7.4, 2.5 mM MgCl₂) and banded on a sucrose step gradient (1 ml nuclei in 65% sucrose TM, 1 ml 60% sucrose TM, 1 ml 55% sucrose TM, 50% sucrose TM, 300 μ l 25% sucrose TM) for one hour at 37,000xg with an SW60 35 rotor. The nuclear band is harvested and diluted to 10% sucrose with TM buffer. Nuclei are pelleted at 37,000xg

using an SW60 rotor for 15 minutes and the pellet resuspended in 1 ml of TM buffer. Aliquots are size fractionated on denaturing polyacrylamide gels and the intracellular localization determined. By comparison to 5 the migration rate of newly synthesized ribozyme, the various fraction containing intact ribozyme can be determined.

To investigate modifications which would lengthen the half-life of ribozyme molecules intracellularly, the cells 10 may be fractionated as above and the purity of each fraction assessed by assaying enzyme activity known to exist in that fraction.

The various cell fractions are frozen at -70°C and used to determine relative nuclease resistances of modified 15 ribozyme molecules. Ribozyme molecules may be synthesized with 5 phosphorothioate (ps), or 2'-O-methyl (2'-OMe) modifications at each end of the molecule. These molecules and a phosphodiester version of the ribozyme are end-labeled with ^{32}P and ATP using T4 polynucleotide 20 kinase. Equal concentrations are added to the cell cytoplasmic extracts and aliquots of each taken at 10 minute intervals. The samples are size fractionated by denaturing PAGE and relative rates of nuclease resistance analyzed by scanning the gel with an Ambis β -scanner. The 25 results show whether the ribozymes are digested by the cytoplasmic extract, and which versions are relatively more nuclease resistant. Modified ribozymes generally maintain 80-90% of the catalytic activity of the native ribozyme when short RNA substrates are employed.

30 Unlabeled, 5' end-labeled or 3' end-labeled ribozymes can be used in the assays. These experiments can also be performed with human cell extracts to verify the observations.

HeLa (CD4 $^+$) and Vero cells are used by many investigators 35 to screen antiviral chemicals in pre-clinical trials. Ribozymes and antisense DNAs depend upon their nuclease stability to maintain therapeutic levels in

infected cells. To design chemical modifications which increase the nuclease stability of ribozymes, we have prepared nuclear, cytoplasmic and membranous lysates from various cell types and compared the relative specific activity (units of nuclease/mg protein) and cation optima (Mg^{2+} , Mn^{2+} , Ca^{2+} or Zn^{2+} -activation) of the nuclease populations within these fractions. Nuclease activities vary significantly among the cell fractions studied (Tables 2 and 3, and Figs. 6a-6f; +++ indicates high 5 nuclease activity, ++ and + indicate lower levels, and - indicates no nuclease activity as tested by standard methodology), but the nuclease population present in HeLa 10 cells was dissimilar to that observed in both monocyte and lymphocyte preparations (Table 4, standard units are noted 15 in the table for comparison only and are not reflective of a specific level of nuclease activity).

HeLa nucleases were maximally active in the presence of added Zn²⁺, while added cation did not enhance nuclease activities in monocyte and lymphocyte lysates. The relative nuclease levels in the monocyte and lymphocyte lysates were 2.2 and 4 times higher, respectively, than in activated HeLa lysates.

Various chemical modifications to ribozymes were tested for their ability to increase nuclease activity while maintaining catalytic activity of the ribozyme. Fig. 7 shows the effects of various modifications upon the catalytic activity of a selected ribozyme. The modifications which decreased activity (1315, 1371, and 1285) were dropped from further analyses. Chemical modifications to ribozymes resulted in cell-specific patterns of ribozyme stability, and 2'-O-methyl sugar substitution gave the best overall enhancement of ribozyme stability across lysates. Relative resistance of ribozymes to digestion by lymphocyte and monocyte cytoplasmic lysates are shown in Fig. 8. The digestion rates of the ribozymes are similar when the ribozymes are labeled at either the 5'- or 3'-ends of the molecule, demonstrating that the degradation is not due to endogenous phosphatase activity in the lysates.

Various reports have suggested that modifications to hammerhead motif ribozymes in the binding arms (stems I and III) will give much enhanced protection from nuclease digestion. As shown in Fig. 9, we observe different results. There appear to be nuclease resistant sites at

the positions 2.4, 2.5, 7, 8, 9, 10.4, and 13. The 2.4, 2.5 and 10.4 position resistance may be specific to the ribozyme tested and more sequences need to be tested before a conclusion can be reached concerning the nuclease 5 sensitivity of these sites, but the positions 7, 8, 9 and 13 are conserved nucleotides in this motif and appear to be sites at which nuclease digestion stops, as demonstrated by the appropriate stable fragments produced in lysate digestion experiments. Interestingly, although 10 there seems to be much more nuclease in the lymphocyte and monocyte lysates, no stable fragments were observed when similar experiments were performed using an activated HeLa cytoplasmic lysate. Observations of ribozyme efficacy in HeLa CD4⁺ cells should be re-examined in lymphocytes before 15 the therapeutic relevance can be determined.

Example 1: HIV tat Ribozymes

The 5' exon of tat contains the following potential cleavage sites: 2 GUC sites, 3 GUA sites, 5 AUC sites, 3 UCC sites, and 5 CUC sites. All 18 sites were examined by 20 computer folding and by RNaseH cleavage assay.

A measure of the accessibility of each site to binding by a 13-mer oligonucleotide was preferred in the following way:

(a) The first 425 nucleotides of the clone V 25 sequence (this clone was made available by Dr. Rossi and includes the 5' tat exon at nucleotides 151-366) was folded on RNAFOLD 4.0 (a generally available program) and examined for the presence of folding domains, i.e., self-contained structures closed by a stem.

(b) For each potential cleavage site, the domain 30 containing that site was folded to confirm that it folded as in part (a); then the domain was refolded while forcing the cleavage site and surrounding nucleotides (11-16 nucleotides in all) to remain unpaired. The difference in 35 these two folding free energies was taken as the cost of

melting out that region for base-pairing by a ribozyme or DNA oligonucleotide.

(c) The lengths of DNA oligonucleotides were adjusted to give predicted delta-G (binding) of -17 to -18 5 kcal/mole. Thus, differences in overall binding energy was predicted to be reflected in the free energy differences calculated in part (b). The calculations are shown in Table 5.

Table 5

[site refers to nucleotide 5' of cleaved phosphate]

Eighteen DNA oligonucleotides were made to target the 18 target sites listed in Table 5. RNaseH experiments were performed using approximately 100 nM body labeled RNA

transcript (clone V), 0.08 U/ μ l RNaseH (excess RNaseH) and a 2x dilution of 1 mM, 10 μ M or 1 μ M DNA oligonucleotide. The results are shown in Table 5. Eight out of 18 sites had greater than 40% cleavage at 5 μ M after 10 minutes incubation. Three ribozymes were designed against the three most active sequences (H332, H337b, H352, see Table 6).

These three ribozymes are shown in Figs. 3A, B and C, labeled respectively HDH, HEH and HFH.

Example 2: Ribozymes Containing Thiophosphate

The purpose of this example was to evaluate the 5 activity of ribozymes containing substitutions of thiophosphate for phosphate at some backbone positions.

Ribozymes to the HIV-1 tat gene were synthesized on an ABI synthesizer using standard phosphoramidite chemistry, however, at steps where thiophosphate was to be 10 incorporated in the backbone the standard oxidation step (involving Iodine) was replaced with an oxidation step utilizing the Beaucage sulfur transfer reagent. Deprotected and desalting RNA was gel purified, eluted, 15 kinased and sequenced to ensure that the sequence was correct. The end-labeled RNA was also treated with H_2O_2 which preferentially promotes cleavage at positions containing thiophosphate.

Ribozyme activity was tested against cleavage of a short (12 nucleotides) end-labeled substrate RNA. 20 Substrate concentration was approximately 1 nM; ribozyme concentration was 5-100 nM; incubation was at 37°C in 75 mM Tris (pH 7.5), 0.1 mM EDTA, 10 mM MgCl₂, for 2-40 minutes. Cleavage extents were determined by gel electrophoresis (PAGE) followed by quantitation on the AMBIS.

25 The ribozymes are shown in Figs. 4A - 4G. The following ribozymes showed essentially 100% activity: r37 (unmodified), r37s2 (1 thio on 5' arm, 2 on 3' arm), r37s4 (3 thio modifications on each arm), s37A (3 modifications on 3' arm), s37B (3 modifications alternating on 3' arm).

30 Ribozymes that are fully modified showed some decrease in activity, for example, s37C (almost completely modified on substrate binding arms) showed a 3x reduction in activity relative to unmodified, s37D (thio modifications in stem I, II and III) showed about a 9x reduction 35 in activity relative to unmodified.

Example 3: 2'-O-methyl-containing Ribozymes

Ribozymes were made on an ABI synthesizer using standard phosphoramidite chemistry with 2'-O-methyl phosphoramidite nucleotides used in place of standard 5 nucleotides. Ribozyme activity was determined in the manner described above with PAGE analysis.

Referring to Fig. 5, a ribozyme containing 2'-O-methyl at all positions that base-pair with substrate (except for the A at the 5' side of stem III) was synthesized. The Kcat/Km for the 2'-O-methyl ribozyme was $44 \times 10^6 \text{ M}^{-1} \text{ min}^{-1}$ compared to $41 \times 10^6 \text{ M}^{-1} \text{ min}^{-1}$ for the unmodified, and 32×10^6 for a thiophosphate modified ribozyme. Thus, the 2'-O-methyl ribozyme retains 100% activity.

15 Example 4: Targeting the LTR and TAT Regions of HIV-1

The following example extends those provided above to show useful ribozymes targeted to the LTR and TAT regions of HIV-1. Details of methodology used herein are provided in Stinchcomb et al., Methods and Compositions for 20 Treatment of Restenosis and Cancer Using Ribozymes, USSN 08/245,466, filed 5/18/94 hereby incorporated by reference herein. Such details are not required to practice the invention. Numbering of bases is according to GenBank 25 Nos. K03455 (HIVHXB2) (numbered from transcription start site).

Screening LTR region for HH Ribozyme Sites:

The LTR is among the most conserved regions within the HIV-1 genome. Also, the LTR region is present in all the transcripts generated during HIV-1 life cycle. So, 30 ribozymes that cleave LTR targets will potentially block HIV replication.

There are 43 potential hammerhead (HH) ribozyme sites within the HIV-1 LTR. Ten hammerhead ribozymes were synthesized based on a) proper folding of the ribozyme

with its target and b) conservation of target sequence among all HIV-1 strains.

RNA Synthesis:

5 Ribozymes with 7/7 binding arms were synthesized using RNA phosphoramidite chemistry. Ribozymes were deprotected and purified as described above.

Target RNA used in this study was 613 nt long and contained cleavage sites for all the 10 HH ribozymes targeted against LTR. A template containing T7 RNA 10 polymerase promoter upstream of LTR target sequence, was PCR amplified from an HIV-1 pro-DNA clone. Other such clones can be readily constructed. Target RNA was transcribed from this PCR amplified template using T7 RNA 15 polymerase. The transcript was internally labeled during transcription by including [α -³²P] CTP as one of the four ribonucleotide triphosphates. The transcription mixture was treated with DNase-1, following transcription at 37°C for 2 hours, to digest away the DNA template used in the transcription. RNA was precipitated with isopropanol and 20 the pellet was washed two times with 70% ethanol to get rid of salt and nucleotides used in the transcription reaction. RNA is resuspended in DEPC-treated water and stored at 4°C.

Ribozyme Cleavage Reactions:

25 Reactions were carried out under ribozyme excess (k_{cat}/K_m) conditions (Herschlag and Cech (1990) *Biochemistry* 29, 10159-10171). Briefly, 1,000 nM ribozyme and 10 nM internally labeled target RNA were denatured separately by heating to 90°C for 2 min in the presence of 50 mM 30 Tris.HCl, pH 7.5 and 10 mM MgCl₂. The RNAs were renatured by cooling to 37°C for 10-20 min. Cleavage reaction was initiated by mixing the ribozyme and target RNA at 37°C. Aliquots of 5 μ l were taken at regular intervals of time and the reaction was quenched by adding equal volume of

stop buffer and freezing on dry ice. The samples were resolved on sequencing gel.

Results:

As shown in Fig. 10, of the ten ribozymes that were tested individually, only four HH ribozymes (568, 581, 631, 696) cleaved the LTR RNA. Other target sites appear to be inaccessible to ribozyme binding and cleavage. Site 568 is also referred to as site 115 and has been targeted for hammerhead ribozyme cleavage by Droubic et al., 66 J. Virol. 1432-1441, 1992 and Heidenreich and Eckstein, 267 J. Biol. Chem. 1904-1909, 1992.

Since 568 HH ribozyme was cleaving its target to a greater extent than the others, we were interested in optimizing the length of binding arms of this HH ribozyme. As shown in Fig. 11, the rate of ribozyme cleavage increased significantly when the length of the binding arm was increased from 12 to 14 base pairs (total). There was no significant improvement in the activity of ribozymes with binding arms longer than 14 base pairs.

Chemical modification of HH ribozymes targeted to a specific site can significantly improve the stability of the ribozyme in human serum. Further, these modifications do not seem to have any significant effect on the catalytic activity of the ribozyme. All the 2' hydroxyl groups within the ribozyme, with the exception of positions U4, G5, A6, U7, G8, G12 and A15.1 (using standard nomenclature, See Fig. 14), were modified with 2'-O-methyl groups. The 2' hydroxyl groups at U4 and U7 were modified with either 2' amino, 2'-C-allyl, 2'-O-methyl or 2'ara-flouro. See Usman et al., 2'-Deoxy 2'-alkylnucleotide containing Nucleic Acid, USSN 08/218,934, filed March 29, 1994, hereby incorporated by reference herein.

Referring to Fig. 12, the 568 HH ribozyme could be stabilized by chemical modification of the sugar moiety of various bases (similar to the ones listed above). The 568

HH ribozyme was extensively modified with one of the following compounds: 2'flouro, 2'amino at the U7 position, araflouro at U4 position, 2'amino at U4 and U7 positions, c-allyl at U4 position. None of the above modifications 5 had any deleterious effect on the ribozyme activity.

Transfection of cells with 568 HH ribozyme (with U4 and U7 positions containing 2'amino modifications) blocks the replication of HIV-1 replication.

Screening TAT region for HH Ribozyme Sites:

10 A region of the TAT mRNA is present in the majority of the transcripts generated during HIV-1 life cycle. So, ribozymes that cleave TAT targets will potentially block HIV replication.

15 There are 54 potential HH ribozyme site within the HIV-1 TAT regions (between 5776 nt and 6044 nt). Nine hammerhead ribozymes were synthesized based on a) proper folding of the ribozyme with its target and b) conservation of target sequence among all HIV-1 strains.

20 RNA synthesis and ribozyme cleavage reactions were carried out as described above. Target RNA used in this study was 422 nt long.

25 As shown in Fig. 13, five sites (5841, 5869, 5878, 5966, 5969) are cleaved more readily than the others. None of these hammerhead sites have previously been targeted.

Screening HIV-1 genome for Hairpin Ribozyme Sites:

Referring to Table VIII and Fig. 15, there are 27 potential hairpin (HP) ribozyme sites in the HIV-1 genome. Ribozymes shown in the table were synthesized and tested. 30 Modifications to various regions of the hairpin structure can be made without deleterious effect, e.g., in those targetted to n.t. positions 565 and 4398 two extra bases can be inserted in place of GGCA (3rd col.) to GGCACA; and GCAG to GCAGUC respectively.

Site 565 within the LTR region (Ojwang et al., (1992) PNAS. USA. 89, 10802-10806; Yu et al., (1993) PNAS. USA. 90, 6340-6344) and 4398 within the POL region of the HIV-1 genome (Joseph and Burke (1993) J. Biol. Chem. 268, 5 24515-24518) have been shown to be accessible to HP ribozyme binding and cleavage. We have also found that HP ribozymes targeted towards 565 and 4398 sites are active.

The best HH and HP ribozymes are shown in Table VII, with their associated cleavage and target sites.

10 Administration of Ribozyme

Selected ribozymes can be administered prophylactically, or to HIV-1 infected patients, e.g., by exogenous delivery of the ribozyme to an infected tissue by means of an appropriate delivery vehicle, e.g., a liposome, a 15 controlled release vehicle, by use of iontophoresis, electroporation or ion paired molecules, or covalently attached adducts, and other pharmacologically approved methods of delivery. Routes of administration include intramuscular, aerosol, oral (tablet or pill form), 20 topical, systemic, ocular, intraperitoneal and/or intrathecal. Expression vectors for immunization with ribozymes and/or delivery of ribozymes are also suitable.

The specific delivery route of any selected ribozyme will depend on the use of the ribozyme. Generally, a 25 specific delivery program for each ribozyme will focus on unmodified ribozyme uptake with regard to intracellular localization, followed by demonstration of efficacy. Alternatively, delivery to these same cells in an organ or tissue of an animal can be pursued. Uptake studies will 30 include uptake assays to evaluate cellular ribozyme uptake, regardless of the delivery vehicle or strategy. Such assays will also determine the intracellular localization of the ribozyme following uptake, ultimately establishing the requirements for maintenance of steady- 35 state concentrations within the cellular compartment containing the target sequence (nucleus and/or cytoplasm).

Efficacy and cytotoxicity can then be tested. Toxicity will not only include cell viability but also cell function.

Some methods of delivery that may be used include:

- 5 a. encapsulation in liposomes,
- b. transduction by retroviral vectors,
- c. conjugation with cholesterol,
- d. localization to nuclear compartment utilizing antigen binding or nuclear targeting site found
- 10 on most snRNAs or nuclear proteins,
- e. neutralization of charge of ribozyme by using nucleotide derivatives, and
- f. use of blood stem cells to distribute ribozymes throughout the body.

15 At least three types of delivery strategies are useful in the present invention, including: ribozyme modifications, particle carrier drug delivery vehicles, and retroviral expression vectors. Unmodified ribozymes, like most small molecules, are taken up by cells, albeit 20 slowly. To enhance cellular uptake, the ribozyme may be modified essentially at random, in ways which reduce its charge but maintains specific functional groups. This results in a molecule which is able to diffuse across the cell membrane, thus removing the permeability barrier.

25 Modification of ribozymes to reduce charge is just one approach to enhance the cellular uptake of these larger molecules. The random approach, however, is not advisable since ribozymes are structurally and functionally more complex than small drug molecules. The structural requirements necessary to maintain ribozyme 30 catalytic activity are well understood by those in the art. These requirements are taken into consideration when designing modifications to enhance cellular delivery. The modifications are also designed to reduce susceptibility 35 to nuclease degradation. Both of these characteristics should greatly improve the efficacy of the ribozyme. Cellular uptake can be increased by several orders of

magnitude without having to alter the phosphodiester linkages necessary for ribozyme cleavage activity.

Chemical modifications of the phosphate backbone will reduce the negative charge allowing free diffusion across 5 the membrane. This principle has been successfully demonstrated for antisense DNA technology. The similarities in chemical composition between DNA and RNA make this a feasible approach. In the body, maintenance of an external concentration will be necessary to drive the diffusion of 10 the modified ribozyme into the cells of the tissue. Administration routes which allow the diseased tissue to be exposed to a transient high concentration of the drug, which is slowly dissipated by systemic adsorption are preferred. Intravenous administration with a drug carrier 15 designed to increase the circulation half-life of the ribozyme can be used. The size and composition of the drug carrier restricts rapid clearance from the blood stream. The carrier, made to accumulate at the site of infection, can protect the ribozyme from degradative 20 processes.

Drug delivery vehicles are effective for both systemic and topical administration. They can be designed to serve as a slow release reservoir, or to deliver their contents directly to the target cell. An advantage of 25 using direct delivery drug vehicles is that multiple molecules are delivered per uptake. Such vehicles have been shown to increase the circulation half-life of drugs which would otherwise be rapidly cleared from the blood stream. Some examples of such specialized drug delivery 30 vehicles which fall into this category are liposomes, hydrogels, cyclodextrins, biodegradable nanocapsules, and bioadhesive microspheres.

From this category of delivery systems, liposomes are preferred. Liposomes increase intracellular stability, 35 increase uptake efficiency and improve biological activity.

Liposomes are hollow spherical vesicles composed of lipids arranged in a similar fashion as those lipids which make up the cell membrane. They have an internal aqueous space for entrapping water soluble compounds and range in size from 0.05 to several microns in diameter. Several studies have shown that liposomes can deliver RNA to cells and that the RNA remains biologically active.

For example, a liposome delivery vehicle originally designed as a research tool, Lipofectin, has been shown to deliver intact mRNA molecules to cells yielding production of the corresponding protein. In another study, an antibody targeted liposome delivery system containing an RNA molecule 3,500 nucleotides in length and antisense to a structural protein of HIV, inhibited virus proliferation in a sequence specific manner. Not only did the antibody target the liposomes to the infected cells, but it also triggered the internalization of the liposomes by the infected cells. Triggering the endocytosis is useful for viral inhibition. Finally, liposome delivered synthetic ribozymes have been shown to concentrate in the nucleus of H9 (an example of an HIV-sensitive cell) cells and are functional as evidenced by their intracellular cleavage of the sequence. Liposome delivery to other cell types using smaller ribozymes (less than 142 nucleotides in length) exhibit different intracellular localizations.

Liposomes offer several advantages: They are non-toxic and biodegradable in composition; they display long circulation half-lives; and recognition molecules can be readily attached to their surface for targeting to tissues. Finally, cost effective manufacture of liposome-based pharmaceuticals, either in a liquid suspension or lyophilized product, has demonstrated the viability of this technology as an acceptable drug delivery system.

Other controlled release drug delivery systems, such as nonoparticles and hydrogels may be potential delivery vehicles for a ribozyme. These carriers have been developed for chemotherapeutic agents and protein-based

pharmaceuticals, and consequently, can be adapted for ribozyme delivery.

Topical administration of ribozymes is advantageous since it allows localized concentration at the site of administration with minimal systemic adsorption. This simplifies the delivery strategy of the ribozyme to the disease site and reduces the extent of toxicological characterization. Furthermore, the amount of material to be applied is far less than that required for other administration routes. Effective delivery requires the ribozyme to diffuse into the infected cells. Chemical modification of the ribozyme to neutralize negative charge may be all that is required for penetration. However, in the event that charge neutralization is insufficient, the modified ribozyme can be co-formulated with permeability enhancers, such as Azone or oleic acid, in a liposome. The liposomes can either represent a slow release presentation vehicle in which the modified ribozyme and permeability enhancer transfer from the liposome into the infected cell, or the liposome phospholipids can participate directly with the modified ribozyme and permeability enhancer in facilitating cellular delivery. In some cases, both the ribozyme and permeability enhancer can be formulated into a suppository formulation for slow release.

Ribozymes may also be systemically administered. Systemic absorption refers to the accumulation of drugs in the blood stream followed by distribution throughout the entire body. Administration routes which lead to systemic absorption include: intravenous, subcutaneous, intraperitoneal, intranasal, intrathecal and ophthalmic. Each of these administration routes expose the ribozyme to an accessible diseased tissue. Subcutaneous administration drains into a localized lymph node which proceeds through the lymphatic network into the circulation. The rate of entry into the circulation has been shown to be a function of molecular weight or size. The use of a liposome or

other drug carrier localizes the ribozyme at the lymph node. The ribozyme can be modified to diffuse into the cell, or the liposome can directly participate in the delivery of either the unmodified or modified ribozyme to 5 the cell. This method is particularly useful for treating AIDS using anti-HIV ribozymes of this invention.

Also preferred in AIDS therapy is the use of a liposome formulation which can deliver oligonucleotides to lymphocytes and macrophages. This oligonucleotide 10 delivery system inhibits HIV proliferation in infected primary immune cells. Whole blood studies show that the formulation is taken up by 90% of the lymphocytes after 8 hours at 37°C. Preliminary biodistribution and pharmacokinetic studies yielded 70% of the injected dose/gm of 15 tissue in the spleen after one hour following intravenous administration. This formulation offers an excellent delivery vehicle for anti-AIDS ribozymes for two reasons. First, T-helper lymphocytes and macrophages are the primary cells infected by the virus, and second, a 20 subcutaneous administration delivers the ribozymes to the resident HIV-infected lymphocytes and macrophages in the lymph node. The liposomes then exit the lymphatic system, enter the circulation, and accumulate in the spleen, where the ribozyme is delivered to the resident lymphocytes and 25 macrophages.

Intraperitoneal administration also leads to entry into the circulation, with once again, the molecular weight or size of the ribozyme-delivery vehicle complex controlling the rate of entry..

30 Liposomes injected intravenously show accumulation in the liver, lung and spleen. The composition and size can be adjusted so that this accumulation represents 30% to 40% of the injected dose. The remaining dose circulates in the blood stream for up to 24 hours.

35 The chosen method of delivery should result in cytoplasmic accumulation in the afflicted cells and molecules should have some nuclease-resistance for optimal

dosing. Nuclear delivery may be used but is less preferable. Most preferred delivery methods include liposomes (10-400 nm), hydrogels, controlled-release polymers, microinjection or electroporation (for ex vivo treatments) and other pharmaceutically applicable vehicles. The dosage will depend upon the disease indication and the route of administration but should be between 100-200 mg/kg of body weight/day. The duration of treatment will extend through the course of the disease symptoms, usually at least 14-16 days and possibly continuously. Multiple daily doses are anticipated for topical applications, ocular applications and vaginal applications. The number of doses will depend upon disease delivery vehicle and efficacy data from clinical trials.

Establishment of therapeutic levels of ribozyme within the cell is dependent upon the rate of uptake and degradation. Decreasing the degree of degradation will prolong the intracellular half-life of the ribozyme. Thus, chemically modified ribozymes, e.g., with modification of the phosphate backbone, or capping of the 5' and 3' ends of the ribozyme with nucleotide analogues may require different dosaging. Descriptions of useful systems are provided in the art cited above, all of which is hereby incorporated by reference herein.

The claimed ribozymes are also useful as diagnostic tools to specifically or non-specifically detect the presence of a target RNA in a sample. That is, the target RNA, if present in the sample, will be specifically cleaved by the ribozyme, and thus can be readily and specifically detected as smaller RNA species. The presence of such smaller RNA species is indicative of the presence of the target RNA in the sample.

Other embodiments are within the following claims.

Claims

1. An enzymatic nucleic acid molecule which cleaves RNA of an immunodeficiency virus in *nef*.
2. An enzymatic nucleic acid molecule which cleaves 5 RNA of an immunodeficiency virus in a region selected from the group consisting of *tar*, *rre* and the 3'LTR region.
3. The enzymatic nucleic acid molecule of claim 1, wherein said RNA molecule is in a hammerhead motif.
4. The enzymatic nucleic acid molecule of claim 1, 10 wherein said RNA molecule is in a hairpin, hepatitis Delta virus, group 1 intron, or RNaseP RNA motif.
5. An enzymatic nucleic acid molecule which cleaves the sequence shown as any of SEQ. ID. NOS. 1-68.
6. The enzymatic nucleic acid molecule of any of 15 claims 1-5, wherein said ribozyme comprises between 5 and 23 bases complementary to the RNA of said gene or region.
7. The enzymatic nucleic acid of claim 6, wherein said ribozyme comprises between 10 and 18 bases complementary to the RNA of said gene or region.
- 20 8. A mammalian cell including an enzymatic nucleic acid molecule of any of claims 1-5.
9. The cell of claim 8, wherein said cell is a human cell.
10. The cell of claim 9, wherein said cell is a T4 25 lymphocyte having a CD4 receptor molecule on its cell surface.

11. An expression vector comprising nucleic acid encoding the enzymatic nucleic acid molecule of any of claims 1-5, in a manner which allows expression of that enzymatic RNA molecule within a mammalian cell.

5 12. A method for treatment of an acquired immunodeficiency disease by administering to a patient an enzymatic nucleic acid molecule of any of claims 1-5.

13. The method of claim 12, wherein said patient is a human, cat or simian.

10 14. A method for providing defective viral particles comprising the step of contacting a cell infected with an immunodeficiency virus with an enzymatic nucleic acid molecule active to cleave a gene required for viral replication or infectivity.

15 15. The method of claim 14, wherein said molecule is active to cleave a gene required for viral protein synthesis.

16. The method of claim 14, wherein said gene is the *nef* or *tat* gene.

20 17. A defective viral particle produced by the method of any of claims 14, 15 or 16.

18. An immunogenic preparation comprising a defective viral particle formed by the method of any of claims 14, 15 or 16.

25 19. A method for immunization against infection by HIV-1, comprising the step of contacting a patient with a vector encoding an enzymatic nucleic acid molecule of any of claims 1-5.

20. Enzymatic nucleic acid molecule which cleaves a substrate sequence shown in Table VII or VIII.

21. Enzymatic nucleic acid molecule having a sequence shown in Table VII or VIII.

INTERNATIONAL SEARCH REPORT

Intern. Application No.
PCT/US 94/08613

A. CLASSIFICATION OF SUBJECT MATTER
IPC 6 C12N15/11 C12N9/00 C12N7/04 A61K48/00 A61K31/70
C12N5/10 C12N15/86

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
IPC 6 C12N A61K

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	US,A,5 144 019 (ROSSI ET AL.) 1 September 1992 cited in the application see examples IV,V see Table 1, sequence number 11 ---	5-13,19
X	WO,A,93 05147 (THE SECRETARY DEPARTMENT OF HEALTH AND HUMAN SERVICES OF THE USA) 18 March 1993 see page 8 - page 11, line 29 see page 45, line 1 - line 30 ---	14-18
Y	---	14-18
		-/-

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

* Special categories of cited documents :

- 'A' document defining the general state of the art which is not considered to be of particular relevance
- 'E' earlier document but published on or after the international filing date
- 'L' document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- 'O' document referring to an oral disclosure, use, exhibition or other means
- 'P' document published prior to the international filing date but later than the priority date claimed

'T' later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

'X' document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

'Y' document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

'&' document member of the same patent family

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US94/08613

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely:
Remark: Although claims 12-13, 19 and 14-16(as far as in vivo methods are concerned) are directed to a method of treatment of (diagnostic method practised on) the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.
2. Claims Nos.: because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

The additional search fees were accompanied by the applicant's protest.

No protest accompanied the payment of additional search fees.
